

To assess urologists' proficiency in the interpretation of multiparametric magnetic resonance imaging (mpMRI). When comparing consultants vs. residents, we found no differences in terms of E-fPB ($p = 0.9$) or in correct identification rates ($p = 0.6$). Data were analyzed according to urologists' hierarchy (UH; resident vs. consultant) and previous experience in fusion prostate biopsies (E-fPB, defined as $n = 125$). Multivariable logistic regression analyses (MVLRA) tested potential predictors of proficiency in mpMRI reading. At MVLRA, only E-fPB reached the status of independent predictor of proficiency in mpMRI reading (OR: 3.4, 95% CI 1.2–9.9, $p = 0.02$) after adjusting for UH and type of institution. Additionally, we tested for differences between non-proficient vs. proficient mpMRI readers
