

The data indicates that 42.5% of actors changed the type of food they order after the COVID-19 epidemic. This could reflect a shift towards healthier options or different preferences grounded on their gestures during the epidemic, similar as increased health mindfulness or life changes. Meanwhile, the larger chance (57.5%) who did not change their food choices may reflect a durability of their former preferences or a lack of significant impact from the epidemic's changes. The lower chance (42.5%) who changed the type of food they order indicates a shift in eating actions towards different or healthier options after the epidemic.
