The commonest, and fastest, way in which pathogens can spread through the body is via the bloodstream. Moreover, tissue fluid can drain directly into lymphatic vessels. However, individual pathogens show a preference to localise in particular organs or tissues that may differ from pathogen to pathogen . The lymphatic vessels form a circulatory system that parallels that of the blood . The circulation of the lymphatic fluid is maintained not by the heart but by the movement of the muscles surrounding the lymphatic vessels; thus lymphatic fluid flows at a much more sluggish rate than blood.
