

The Earth's climate has changed several times throughout history. Deforestation contributes to global warming and leads to carbon dioxide remaining in the atmosphere, and as it accumulates, it produces a layer in the atmosphere that blocks the radiation coming from the sun. Livestock farming requires large portions of land to raise animal herds and grow livestock crops to meet consumer needs. According to the National Aeronautics and Space Administration (NASA), there have been seven cycles of warming and cooling in the last 650,000 years. The third reason for urbanization is the process of removing a large area of land to build more accommodation, recreational and agricultural uses by more than 80%.
