

The recycling process is used to get rid of waste that poses a threat to the environment and human health. For example, plastic waste in the sea kills millions of marine organisms annually. One of the benefits of recycling is preserving the environment, protecting natural resources, creating new job opportunities and reducing production costs. Recycling takes place on some materials such as iron, aluminum, steel, plastic, glass, paper and some electronic materials. Glass and metals are recycled to make new products, tires are recycled to make rubber materials, while newspapers and magazines are recycled into new paper and cardboard.
